JPA ANNOTATIONS	11

Step 1: Understand Spring Boot

1. View the pom.xml file that has spring boot starter parent.

It is a special starter project that provides default configurations for our application and a complete dependency tree to quickly build our Spring Boot project.

It also provides default configurations for Maven plugins, such as maven-failsafe-plugin, maven-jar-plugin, maven-surefire-plugin, and maven-war-plugin.

Beyond that, it also inherits dependency management from spring-boot-dependencies, which is the parent to the spring-boot-starter-parent.

2. @SpringBootApplication on the class with the main method:

This annotation is used to enable three features, that is:

- a. @EnableAutoConfiguration: enable Spring Boot's auto-configuration mechanism
 - b. @ComponentScan: enable @Component scan on the package where the application is located (see the best practices)
 - c. @Configuration: allow to register extra beans in the context or import additional configuration classes
3. Run the application, you should see the error with respect to database configuration. This is the default behaviour of spring boot. It sees mysql dependency but did not find database connection parameter information.
 4. Open application.properties file within the resources folder and add the database related connection parameters:

windows users use 3306 as port number

#spring.datasource.url=jdbc:mysql://localhost:3306/java

spring.datasource.url=jdbc:mysql://localhost:8889/java

spring.datasource.username=root

spring.datasource.password=root

spring.datasource.driverClassName=com.mysql.cj.jdbc.Driver

below property specifies the dialect to use

spring.jpa.properties.hibernate.dialect = org.hibernate.dialect.MySQL8Dialect

spring.sql.init.platform=mysql

below property if used will perform DDL operations to create table

spring.jpa.generate-ddl=true

below property if used will show the sql queries generated by hibernate

spring.jpa.show-sql=true

5. Following the package structure is very important with spring boot for it to follow the default configurations.

Step 2: Understand DI in spring boot

6. Copy the NotificationService, IMessageProvider and StringMessageProvider along with annotations within com.boot.demo.service folder.
7. Now run the application and you will notice the beans created as output from constructor will be printed
8. To get the reference of spring context update the main method as follows:

```
ApplicationContext context = SpringApplication.run(SpringBootDemo.class, args);
```

9. Now once you have the context, get the bean reference using context.getBean and will be able to call respective methods

Step 3: Create java entities and tables

1. Create below classes in the com.demo.entity folder with respective annotations to tell hibernate to map with database tables :

```
@Entity
public class Address {

    @Id
    @GeneratedValue(strategy = GenerationType.IDENTITY)
    private int aid;
    private String city;
    private String country;
    @Column(name=="pincode")
    private String zipcode;

    @OneToOne
    @JoinColumn(name="empid")
    private Employee employee;

    // getters and setters
    // constructor
}
```

```
@Entity
public class Employee {
    @Id
    @GeneratedValue(strategy = GenerationType.IDENTITY)
    @NotNull
    private int eid;
    private String ename;
    private String email;
    private String phone;
    @Size(min = 8, max=15)
```

```

        private String password;

        @OneToOne(mappedBy = "employee" , cascade = {CascadeType.REMOVE})
        private Address address;

        // getters and setters
        // constructor
    }

@Entity
public class Book {

    @Id
    @GeneratedValue(strategy = GenerationType.IDENTITY)
    private int bookid;
    private String title;
    private int year;

    @ManyToOne
    @JoinColumn(name="authorid")
    Author author;

    // getters and setters
    // constructor

    @Override
    public String toString() {
        return "Book [bookid=" + bookid + ", title=" + title + ", year=" + year + "];"
    }
}

@Entity
public class Author {

    @Id
    private int aid;
    private String name;
    @OneToMany(mappedBy = "author")
    Set<Book> books;
}

```

2. Once the entities are created, run the main class, see the console where it shows the queries generated by spring boot and see the database where tables are created

Step 4: CrudRepository, JpaRepository, PagingAndSortingRepository

1. By extending the interface, we get the most relevant CRUD methods for standard data access available in a standard DAO.

```
public interface AddressRepository extends JpaRepository<Address, Integer> {  
}
```

```
public interface EmployeeRepository extends JpaRepository<Employee, Integer>  
{  
}
```

```
public interface BookRepository extends JpaRepository<Book, Integer> {  
}
```

```
public interface AuthorRepository extends JpaRepository<Author, Integer> {  
}
```

Step 5: service layer

1. Create EmployeeService class in service folder and inject respective dependencies for crud operations

```
@Service  
public class EmployeeService{  
  
    @Autowired  
    private EmployeeRepository employeeRepository;  
  
    @Autowired  
    private AddressRepository addressRepository;  
}
```

Step 6: Insert Query

2. Create method in EmployeeService class to insert employee record:

```
public Employee insertEmployee(Employee employee) {  
    Employee savedEmployee = this.employeeRepository.save(employee);  
    return savedEmployee;  
}
```

3. To test the above method in the main class, update with foll code:

```
EmployeeService eservice = context.getBean(EmployeeService.class);  
Employee emp = new Employee();  
emp.setEname("Shalini");  
emp.setEmail("shalini@test.com");
```

```
emp.setPassword("shalini123");
emp.setPhone("9898989898");
eservice.insertEmployee(emp);
```

4. Create method in EmployeeService class to insert address record. Since address cannot exist without employee, hence need to check if employee exist whose address need to be saved. If employee exists, then address object should be associated with employee id before insert.

```
public Address insertAddress(Address address, int empid) {
    Optional<Employee> optional = employeeRepository.findById(empid);
    if(optional.isPresent()){
        // associate employee and address
        address.setEmployee(optional.get());
        Address sAddress = this.addressRepository.save(address);
        return sAddress;
    }
    throw new EntityNotFoundException("Employee with id "+empid+" does not exist and hence cannpt save the address");
}
```

5. To test the above method add below code in main method:

```
Address addr = new Address();
addr.setCity("Delhi");
addr.setCountry("India");
addr.setZipcode("989898");
// make sure employee with id 1already exists, else it will throw exception
employeeService.insertAddress(addr,1);
```

Step 7: Transaction Management

1. Add @EnableTransactionManagement in the class with main method
2. Below method is created if need to save employee and address. If address is null then employee record should not be inserted.

```
@Transactional
public Employee insertEmployeeAndAddress(Employee employee) {

    if(this.employeeRepository.existsById(employee.getId()))
        throw new EntityExistsException("Employee "+employee.getId()+" already exist");

    Employee savedEmployee = this.employeeRepository.save(employee);

    Address address = employee.getAddress();
    if(address == null)
        throw new RuntimeException("ERROR could not insert address");
    address.setEmployee(savedEmployee);
    Address savedAddress = this.addressRepository.save(address);
    savedEmployee.setAddress(savedAddress);
}
```

```

        return savedEmployee;
    }

```

test the above code in main method as follows:

```

Address addr = new Address();
addr.setCity("Delhi");
addr.setCountry("India");
addr.setZipcode("989898");

Employee emp = new Employee();
emp.setEname("Sia");
emp.setEmail("sia@test.com");
emp.setPassword("sia12323");
emp.setPhone("9898989898");
// Uncomment below line, employee and address both will be saved. If commented since address
// null, employee will also be not inserted since we used @Transactional
//emp.setAddress(addr);
try {
    Employee e = employeeService.insertEmployee(emp);
} catch (Exception e) {
    System.out.println(e.getMessage());
}

```

Step 8: Select Query

6. Update EmployeeService class for select:

```

public Employee getEmployeeById(int eid) {
    System.out.println("Emp service "+eid);
    return this.employeeRepository.findById(eid)
        .orElseThrow(() -> new EntityNotFoundException("Employee "+eid+"
not found"));
}

```

test the above code in main method

```

public List<Employee> getEmployees(){
    List<Employee> employees = new ArrayList<Employee>();
    this.employeeRepository.findAll().forEach(employees::add);
    return employees;
}

```

test the above code in main method

Step 9: Update Query

7. Update EmployeeService class for update:

```
public Employee updateEmployee(Employee employee) {
    if(!this.employeeRepository.existsById(employee.getId()))
        throw new EntityNotFoundException("Employee
"+employee.getId()+" not found and cannot be updated");
    return this.employeeRepository.save(employee);
}
```

test the above code in main method

Step 10: Delete Query

8. Update EmployeeService class for delete:

```
public boolean deleteEmployee(int eid) {
    if(!this.employeeRepository.existsById(eid))
        throw new EntityNotFoundException("Employee "+eid+" not found
and cannot be deleted");
    this.employeeRepository.deleteById(eid);
    return true;
}
```

test the above code in main method

Step 11: JPA Query methods

1. To create your own queries based on different columns apart from the id , go through below link:

<https://docs.spring.io/spring-data/jpa/reference/jpa/query-methods.html>

2. Lets create a jpa query to get employee by email. Add below code in EmployeeRepository interface

```
public Employee findByEmail(String email);
```

3. Update EmployeeService class to invoke the above method and return employee by email

```
public Employee findEmployeeByEmail(String email){
    return this.employeeRepository.findByEmail(email);
}
```

4. To search for employee address by employee email, add below code in AddressRepository

```
public Address findByEmployeeEmail(String email);
```

5. Create method in service class to test above method:

```
public Address findEmployeeAddressByEmail(String email){
    return this.addressRepository. findByEmployeeEname (email);
}
```

test the above code in main method

Step 12: @Query annotation

1. @Query annotation is used to create custom queries for which method signature is not available
2. To delete address of employee by employee id, need to retrieve the address id for the employee and delete address. Update AddressRepository as follows:

```
@Query("select aid from Address where empid=:id")
public Integer findAddressIdByEmployeeEid(int id);
```

3. Update EmployeeService as follows:

```
public boolean deleteAddressByEmployeeId(int eid) {

    if(!this.employeeRepository.existsById(eid))
        throw new EntityNotFoundException("Employee "+eid+" not found and
        cannot be deleted");

    Integer addressid = addressRepository.findAddressIdByEmployeeEid(eid) ;
    System.out.println("address id "+addressid);
    if(addressid!= null){
        this.addressRepository.deleteById(addressid);
    }
    return true;
}
return false;
}
```

4. To validate employee credentials valid or not when email and password is passed to the program, we need query that returns password for email id if it exists else returns null. Update the EmployeeRepository as follows:

```
@Query("select password from Employee u where email=:email")
public String findPasswordByEmail(String email);
```

5. Update EmployeeService as follows:

```
public boolean loginEmployee(String email, String password) throws
InvalidCredentialsException
{
    String pwd = this.employeeRepository.findByEmail(email);
    if(pwd!=null)
    {
```

```

        //Employee emp = opt.get();
        if(pwd.equals(password))
            return true;
    }
    throw new InvalidCredentialsException("Invalid credentials, Please try
again");
}

```

test the above code in main method

Step 13: Pagination and Sorting

1. To fetch employees pagewise, update EmployeeService as follows:

```

public Page<Employee> getFilteredEmployees(Integer pageno, Integer size){

    Pageable pageable = PageRequest.of(pageno, size);

    List<Employee> employees = new ArrayList<Employee>();
    return this.employeeRepository.findAll(pageable);

}

```

2. In main method just insert few dummy emp records as follows:

```

for(int i=1;i<=50;i++)
{
    Employee e1 = new Employee();
    e1.setName("Emp "+i);
    e1.setEmail("emp"+i+"@test.com");
    e1.setPassword("emp"+i);
    e1.setPhone(i+"234567890");
    Address a1 = new Address();
    a1.setCity("city "+i);
    a1.setCountry("country "+i);
    a1.setZipcode(i+"234");
    e1.setAddress(a1);
    employeeService.insertEmployee(e1);
}

```

test the above code in main method

Step 14: Appendix

JPA ANNOTATIONS

1. **@Entity** : used at the class level and marks the class as a persistent entity. It signals to the JPA provider that the class should be treated as a table in the database
2. **@Id**: indicating the member field below is the primary key of the current entity.
3. **@GeneratedValue** : This annotation is generally used in conjunction with **@Id** annotation to automatically generate unique values for primary key columns within our database tables.
4. The **@GeneratedValue** annotation provides us with different strategies for the generation of primary keys which are as follows :
 - a. **GenerationType.IDENTITY**: This strategy will help us to generate the primary key value by the database itself using the auto-increment column option. It relies on the database's native support for generating unique values.
 - b. **GenerationType.AUTO**: This is a default strategy and the persistence provider which automatically selects an appropriate generation strategy based on the database usage.
 - c. **GenerationType.TABLE**: This strategy uses a separate database table to generate primary key values. The persistence provider manages this table and uses it to allocate unique values for primary keys.
 - d. **GenerationType.SEQUENCE**: This generation-type strategy uses a database sequence to generate primary key values. It requires the usage of database sequence objects, which varies depending on the database which is being used.
5. **@Column** : used to customize the mapping of a specific field to a database column. While JPA automatically maps most fields based on naming conventions, the **@Column** annotation provides developers with greater control over the mapping process.
6. **@OneToOne**: is used to associate one JAVA object with another JAVA object.
7. **@JoinColumn** annotation is used to define a foreign key with the specified name
8. **@JoinTable** annotation in JPA is used to customize the association table that holds the relationships between two entities in a many-to-many relationship. This annotation is often used in conjunction with the **@ManyToMany** annotation to define the structure of the join table.
